Abstract #

## Summary

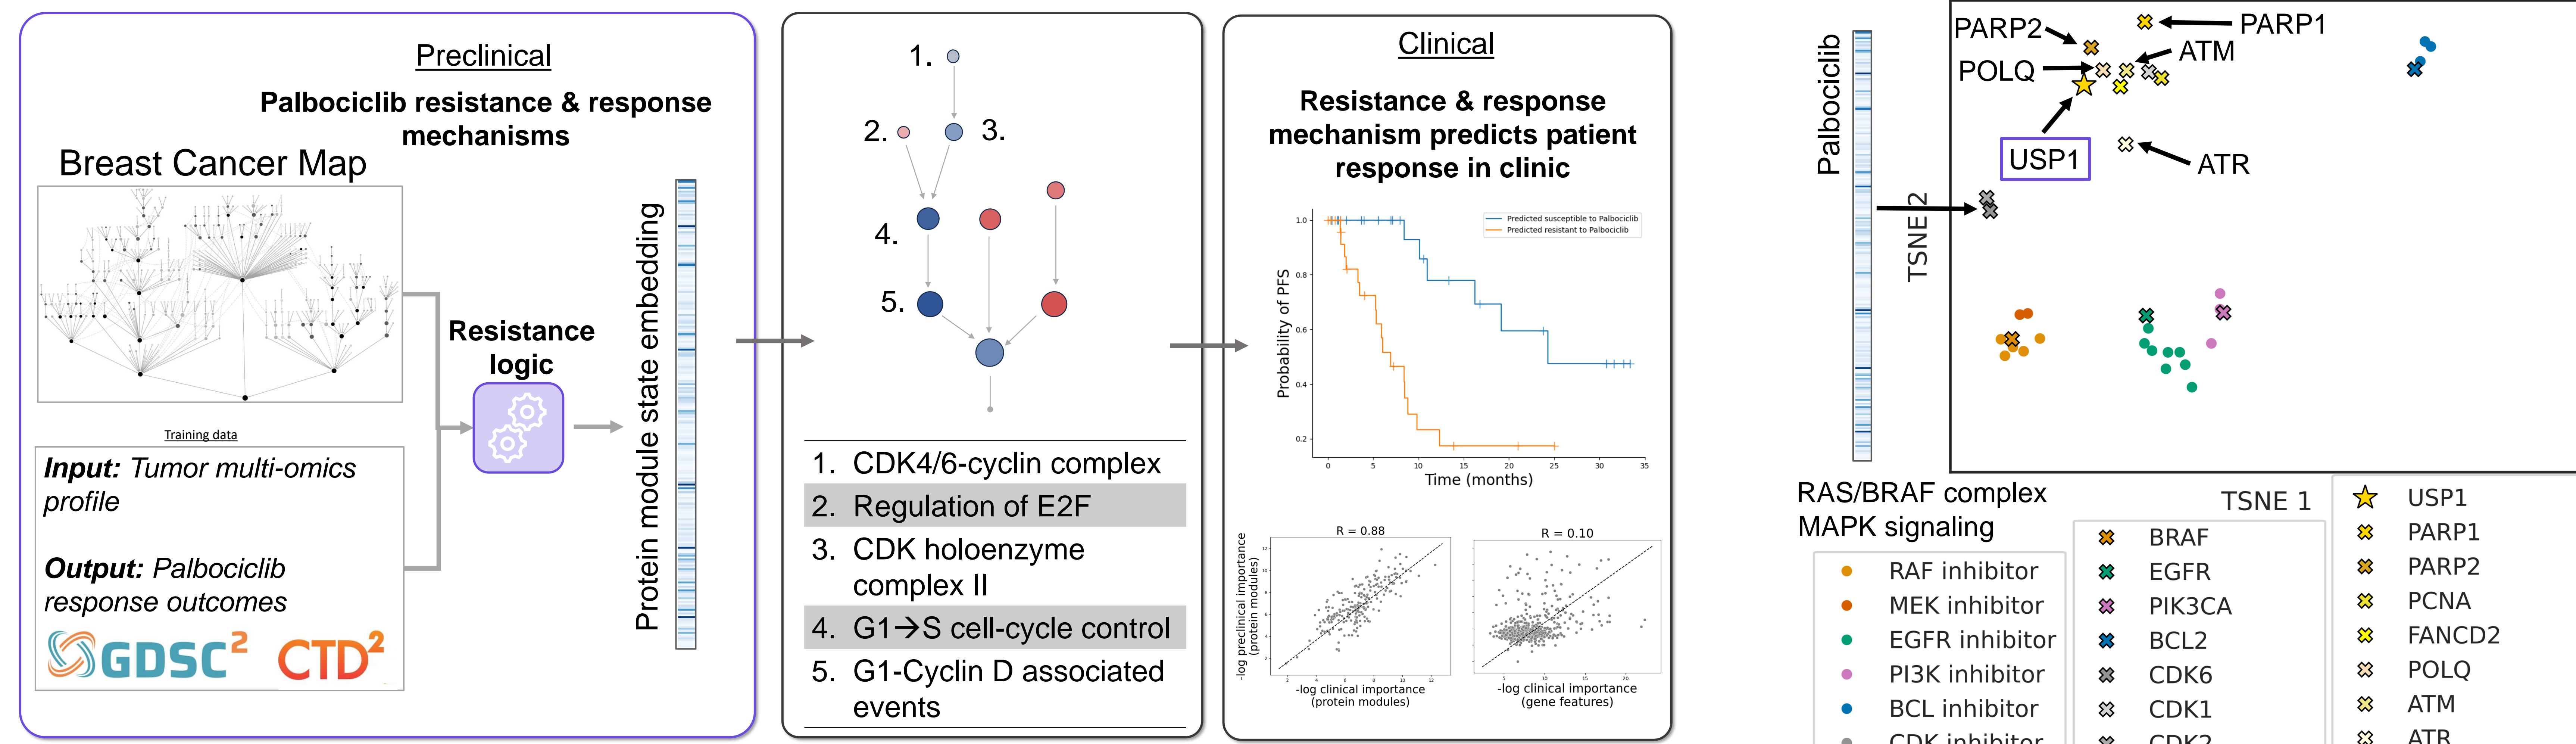

**Background:** Comprehensively understanding a drug's mechanisms of response is critical to identify biomarkers predictive of efficacy, prevent resistance, and design rational combinations.

**Methods:** Serinus Bio has developed an AI platform that systematically learns mechanisms of response & resistance for a drug of interest by leveraging disease-specific maps of cellular architecture.

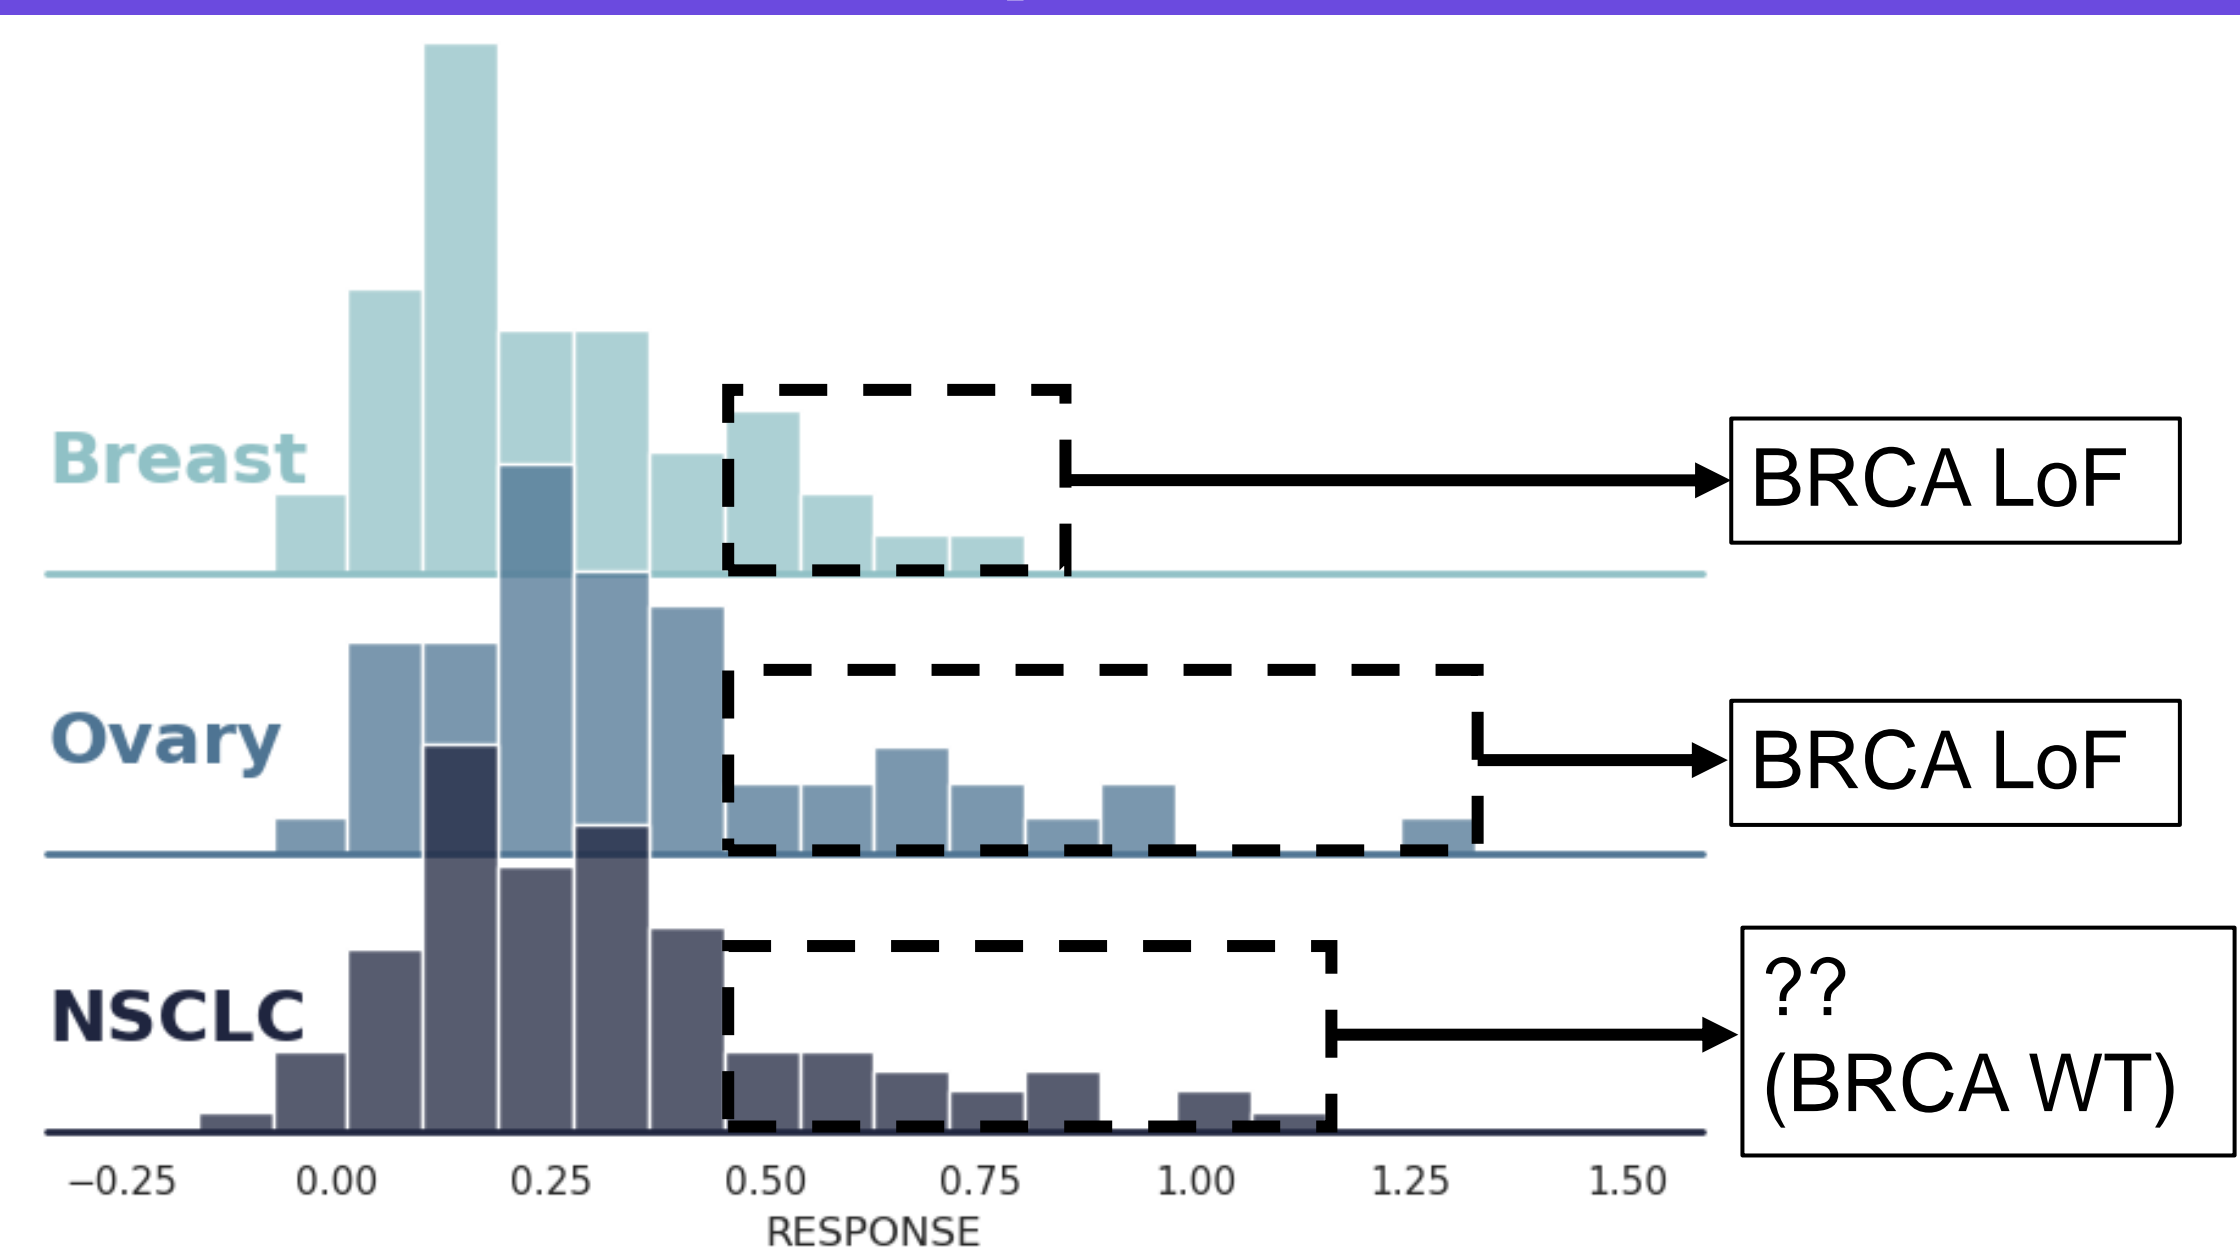

**Results:** Learned mechanisms for ~20K drugs & targets capture key functional relationships. Applying the platform to TNG348, a highly selective USP1 inhibitor, we identified & validated cellular mechanisms explaining >50% of variation in drug response across lung cancer cell lines & PDX models. Response mapping enabled the development of a predictive biomarker logic and potential rational combinations.

**Conclusions:** The Serinus Bio platform is an integrated computational-experimental approach to map drug response mechanisms & design strategies to maximize therapeutic potential.

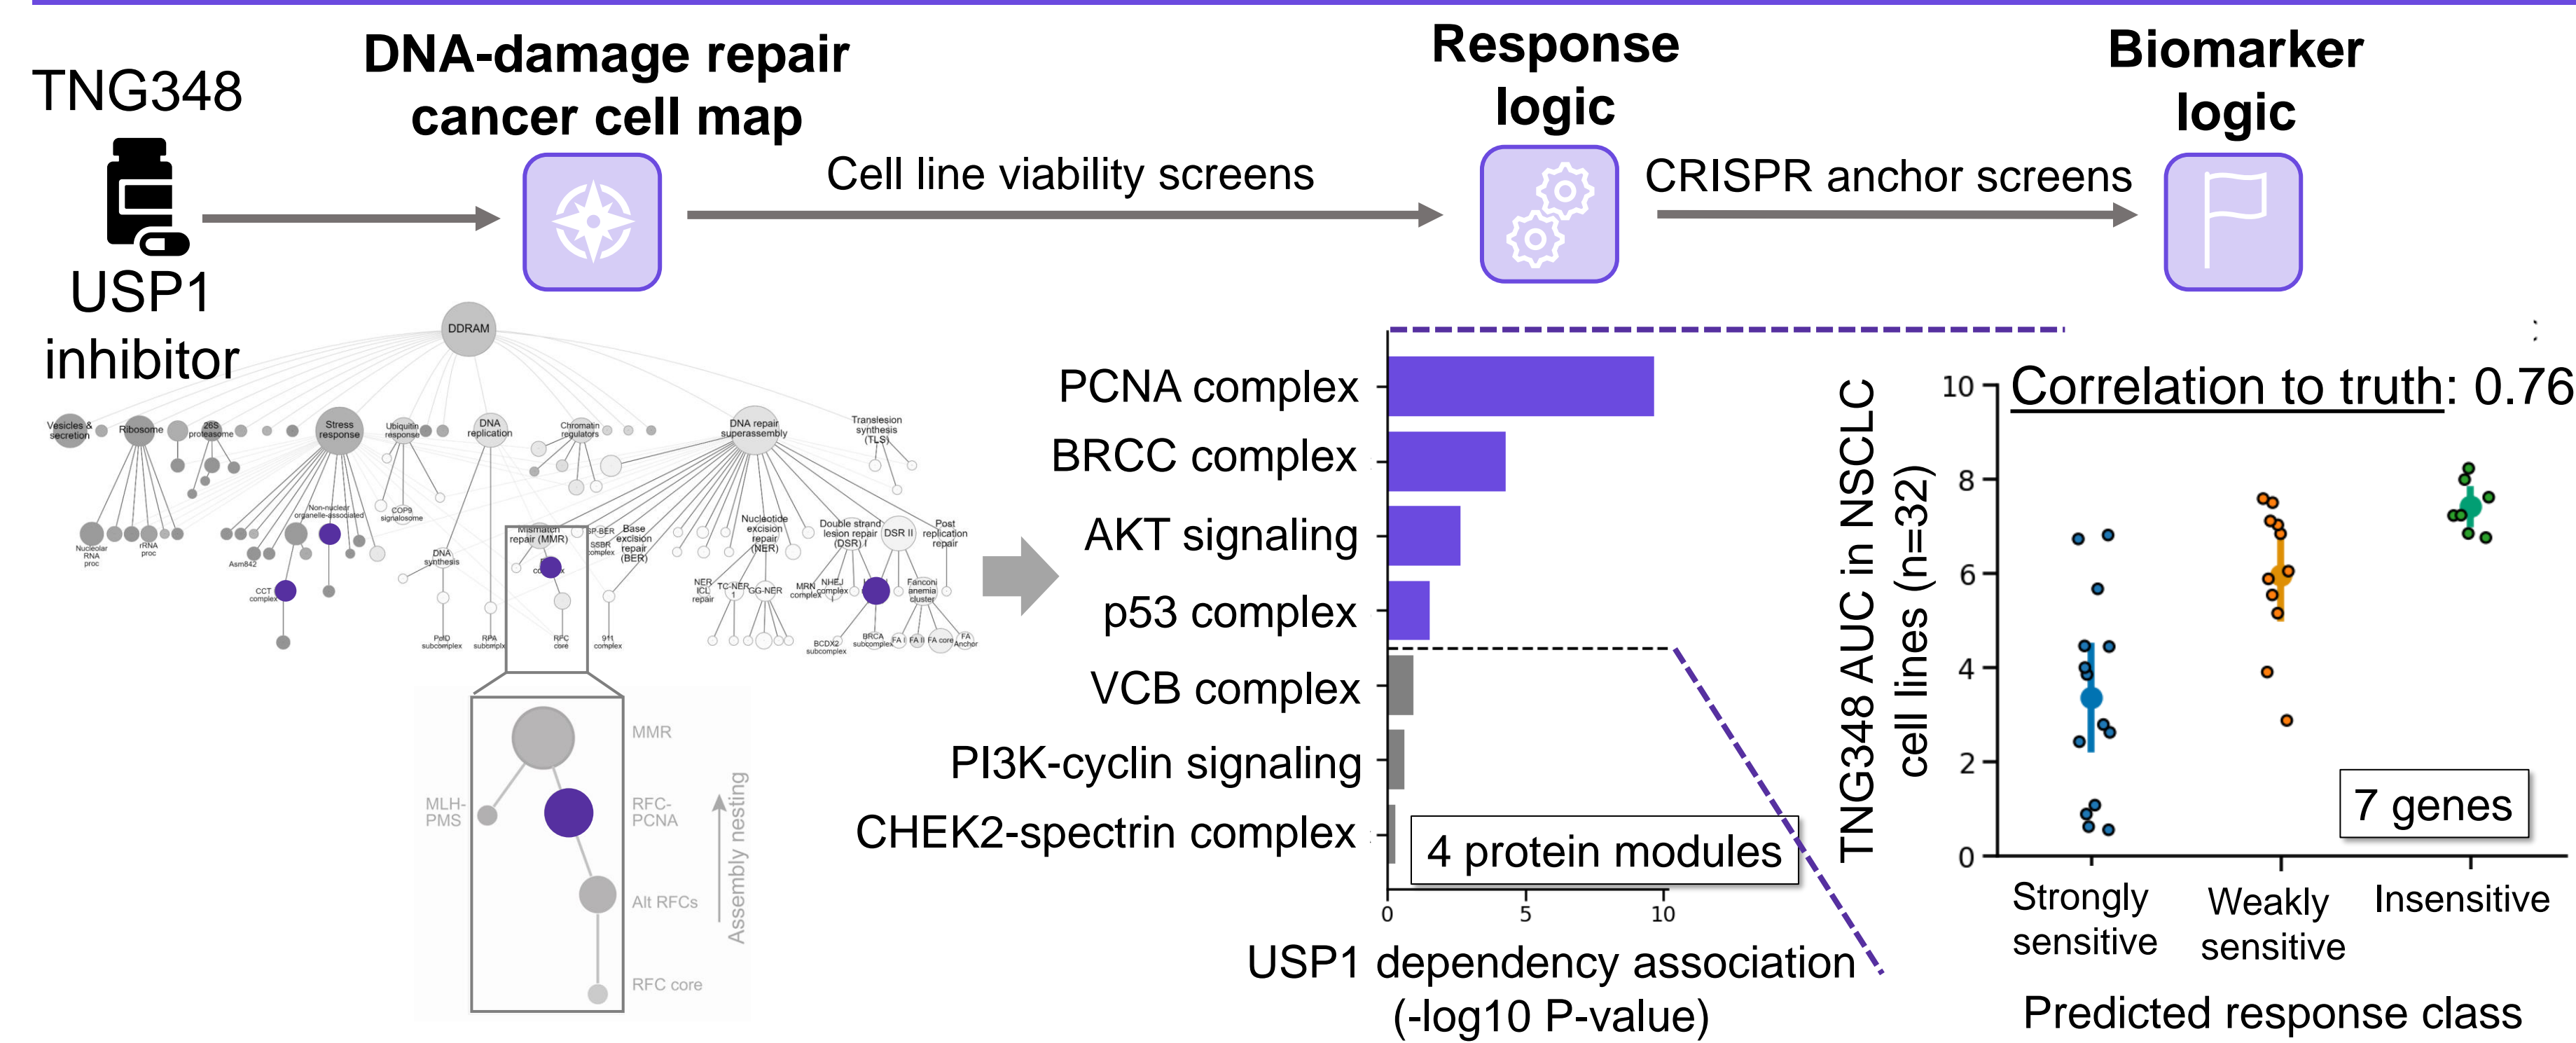

## The Serinus Bio Platform learns clinically relevant response & resistance mechanisms across drugs & targets

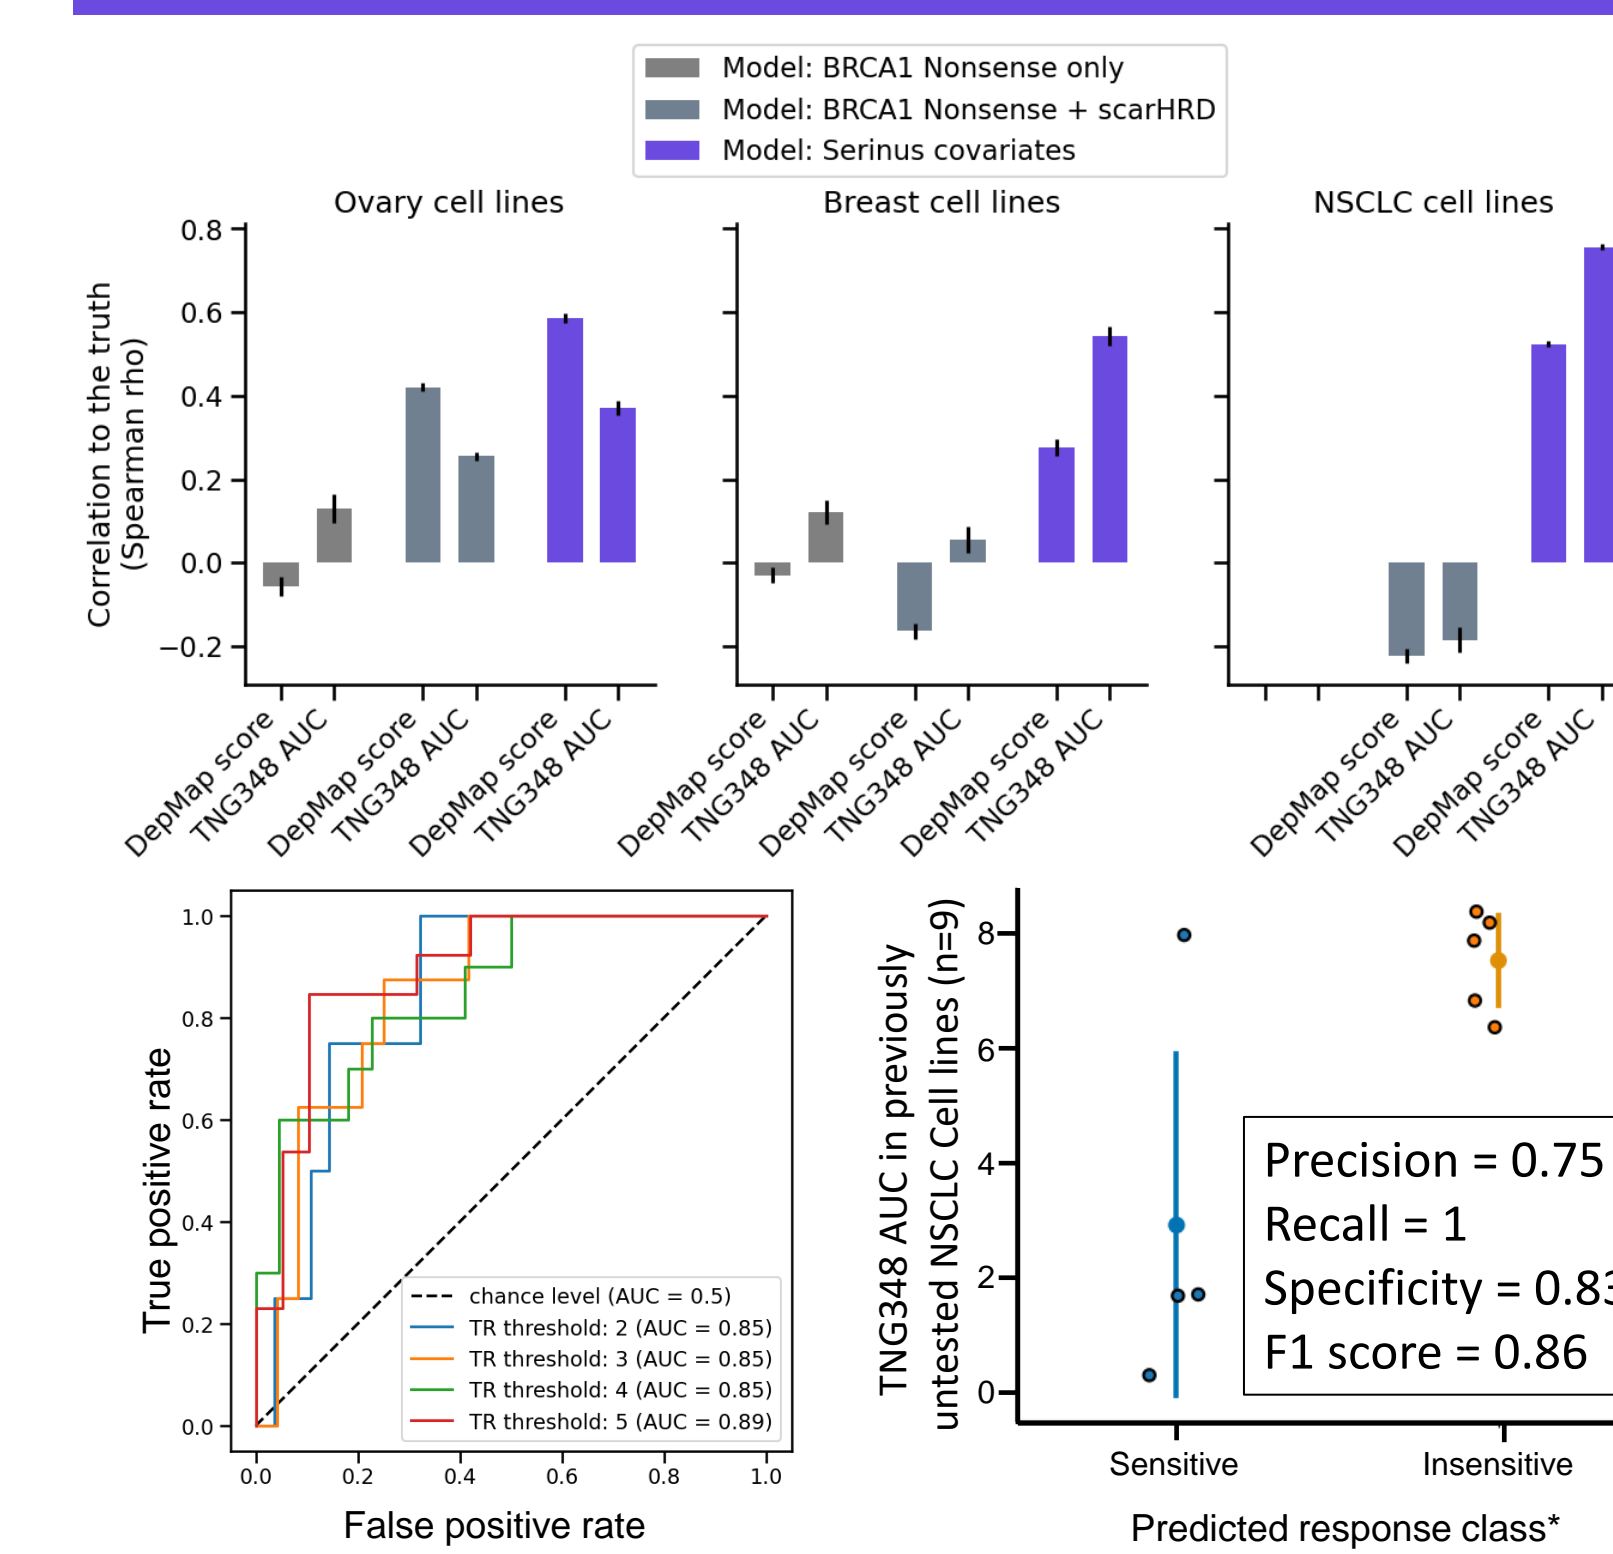

## NSCLC cell lines are selectively dependent on USP1 without a predictive biomarker

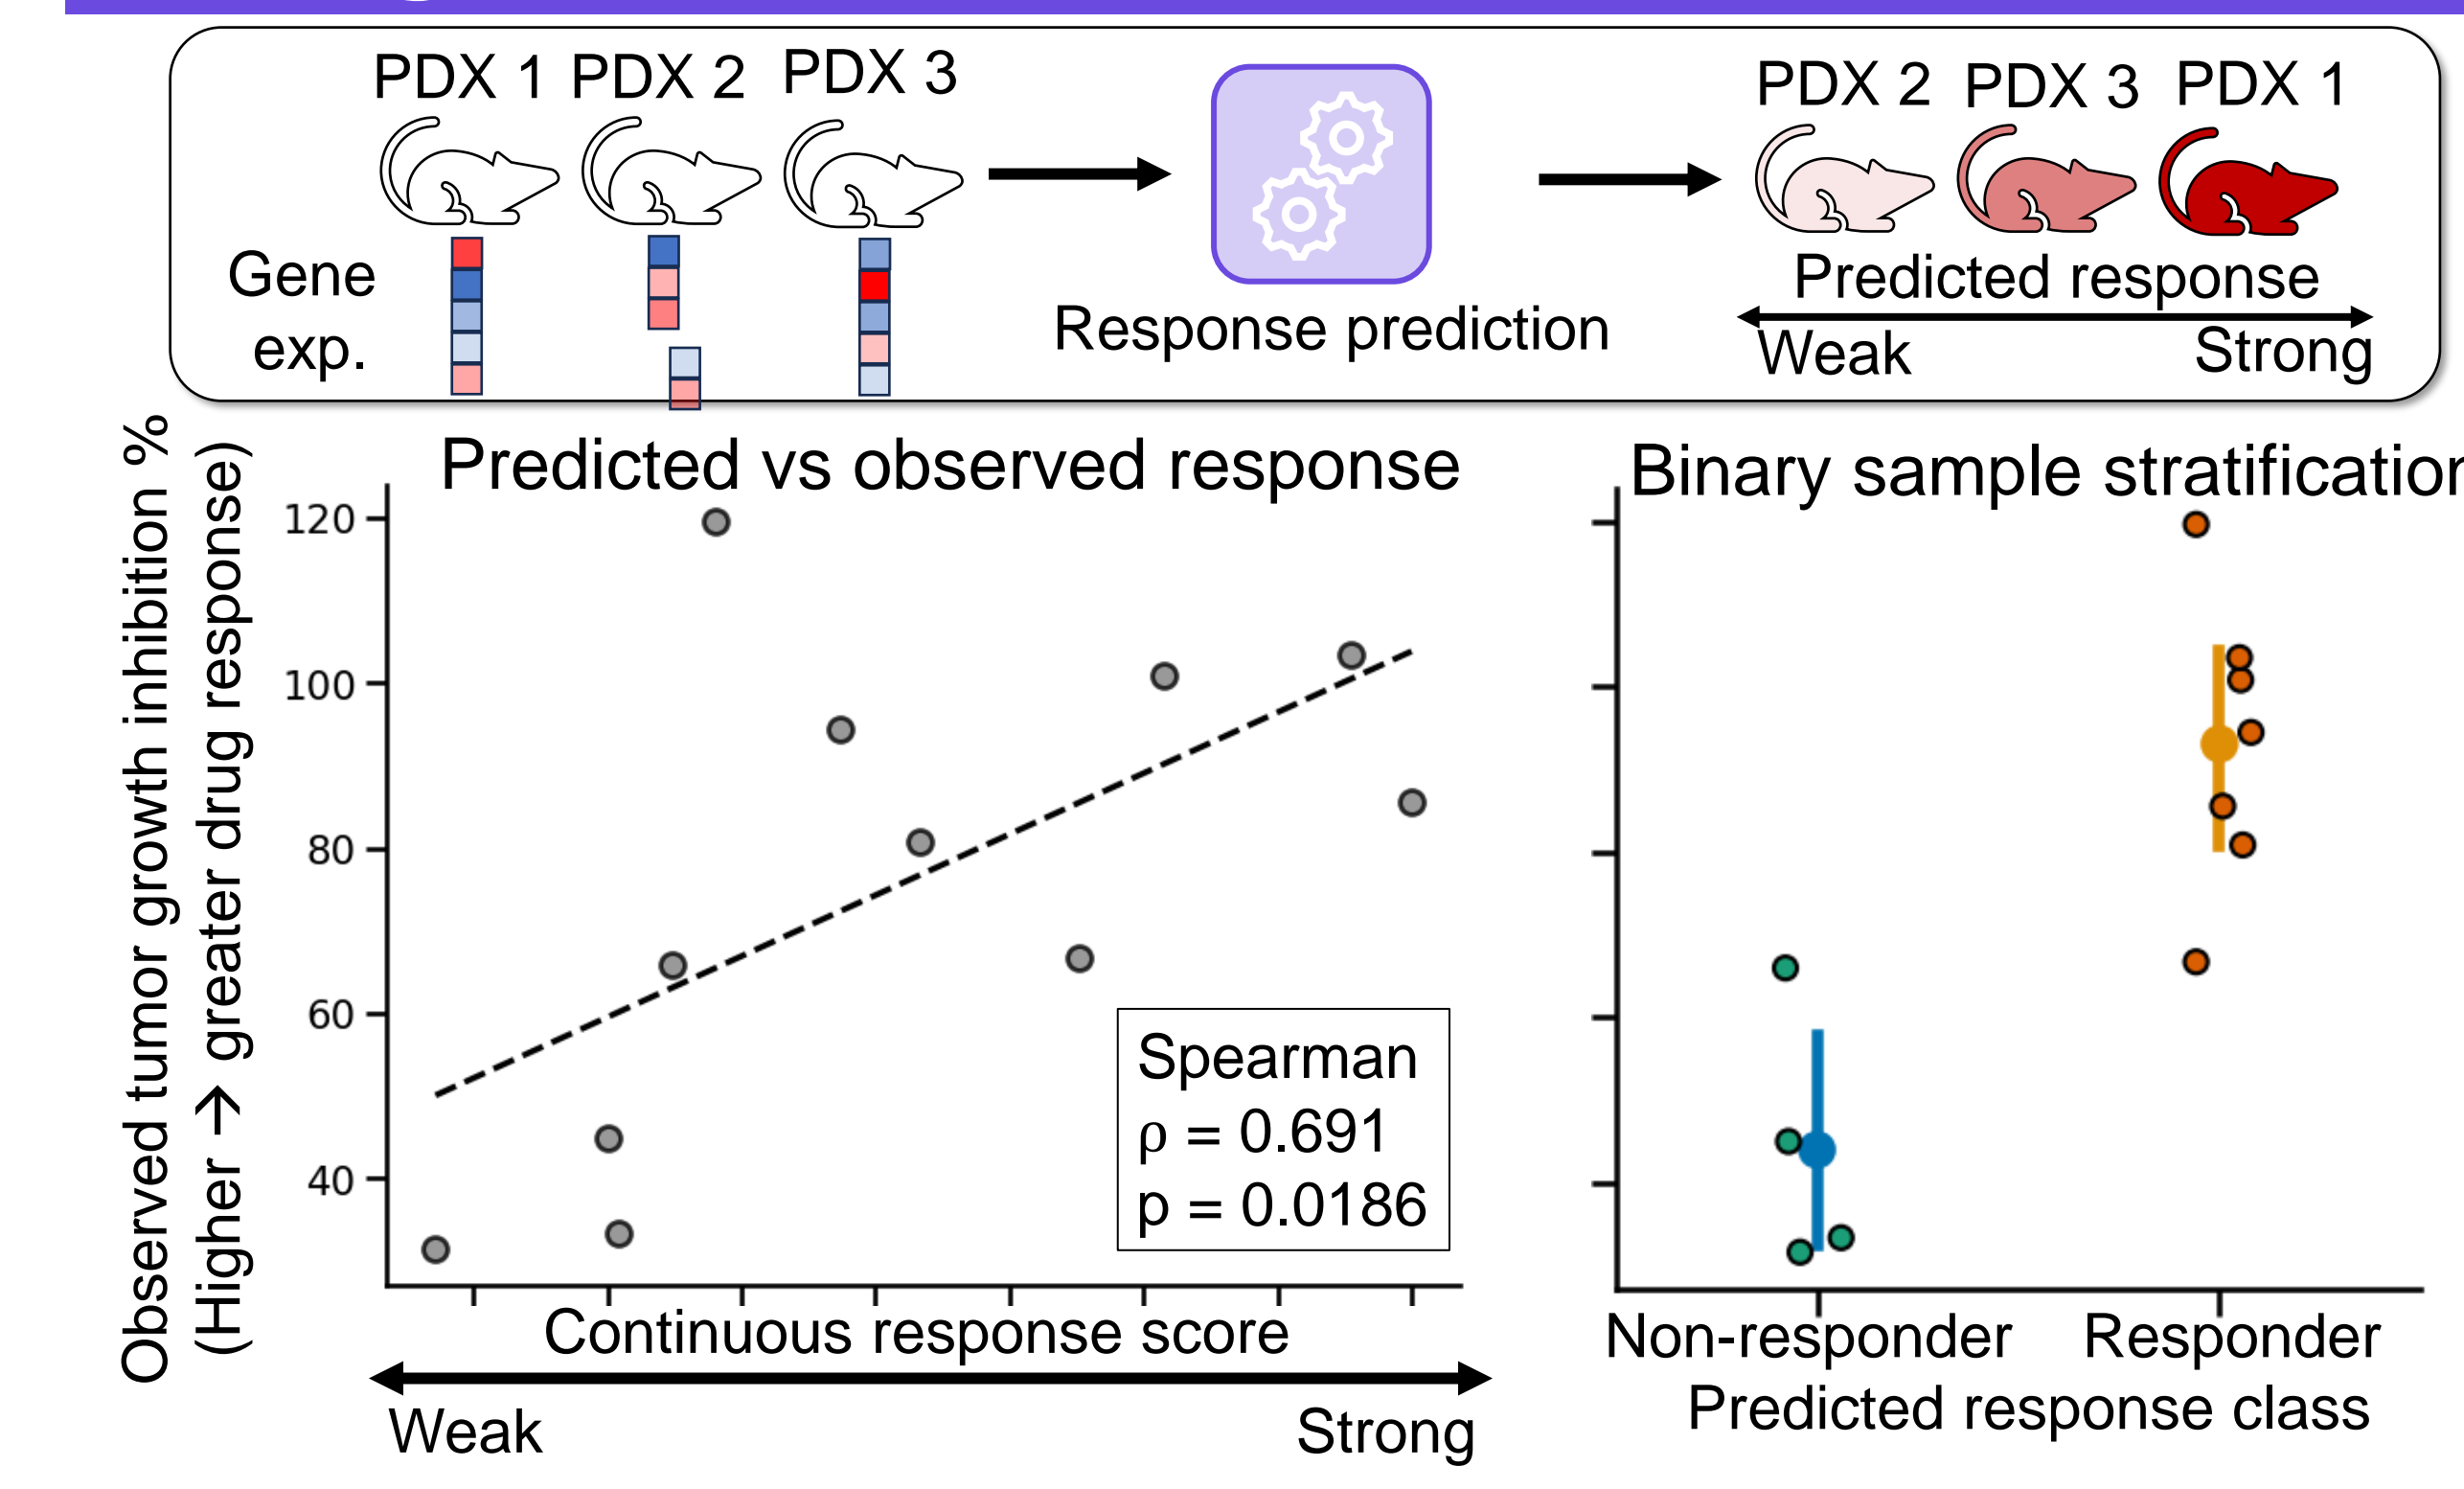

## DDR protein modules predict lung cancer USP1i response

## Biomarkers generalize to untested cell lines

## Biomarker model predicts USP1i response in lung cancer PDX models

## Biomarker logic identifies putative responsive LUAD population

## PCNA knockdown sensitizes lung cancer cell lines to USP1 inhibition
